ABSTRACT. The spread of human resources built on innovation will be accelerated by the formation of new business sectors, knowledge, and skills and the rise of high-value-added manufacturing. Identifying the most significant environmental pollutants and how they affect sustainable human development and addressing the Iraqi environment's reality to remediate this pollution using current ways. The global climate in general and the Iraqi environment face numerous challenges resulting from unregulated natural resource exploitation, which resulted in significant waste in these responses due to the adverse effects of environmental pollution, negatively affecting both sustainable development and the ecosystem. The findings suggest that innovation-driven human resource analysis will be prioritized in emerging nations. Training human resources in this environment will be critical in the future, as shown by Japan and South Korea. This study thoroughly examines data collected in Iraq and other developing nations.
